

# Computational Brain Anatomy

John Ashburner

Wellcome Trust Centre for Neuroimaging, 12 Queen Square, London, UK.

#### Overview

#### Voxel-Based Morphometry

- Morphometry in general
- Volumetrics
- VBM preprocessing followed by SPM
- Tissue Segmentation
- Diffeomorphic Registration
- Longitudinal Registration
- Multivariate Shape Models

## Measuring differences with MRI

- What are the significant differences between populations of subjects?
- What effects do various genes have on the brain?
- What changes occur in the brain through development or aging?
- A significant amount of the difference (measured with MRI) is anatomical.

There are many ways to model differences.

- Usually, we try to localise regions of difference.
  - <sup>•</sup> Univariate models.
  - Using methods similar to SPM
  - Typically localising volumetric differences
- Some anatomical differences can not be localised. Need multivariate models.
  - Differences in terms of proportions among measurements.
  - Where would the difference between male and female faces be localised?
- Need to select the best model of difference to use, before trying to fill in the details.

### Voxel-Based Morphometry

- Based on comparing regional volumes of tissue.
- Produce a map of statistically significant differences among populations of subjects.
  - e.g. compare a patient group with a control group.
  - or identify correlations with age, test-score etc.
- The data are pre-processed to sensitise the tests to regional tissue volumes.
  - Usually grey or white matter.

Suitable for studying focal volumetric differences of grey matter.

#### Volumetry

**T1-Weighted MRI** 

**Grey Matter** 

Template

#### "Modulation" – change of variables.

**Deformation Field** 

Jacobians determinants Encode relative volumes.

# Smoothing

Each voxel after smoothing effectively becomes the result of applying a weighted region of interest (ROI).

#### Before convolution

#### Convolved with a circle

#### Convolved with a Gaussian

# VBM Pre-processing in SPM12

- Use Segment for characterising intensity distributions of tissue classes, and writing out "imported" images that Dartel can use.
- Run Dartel to estimate all the deformations.
- Dartel warping to generate smoothed, "modulated", warped grey matter.
- Statistics.

#### "Globals" for VBM

- Shape is really a multivariate concept
  - Dependencies among different regions
- SPM is mass univariate
  - Combining voxel-wise information with "global" integrated tissue volume provides a compromise
  - Either ANCOVA or proportional scaling.

(ii) is globally thicker, but locally thinner than (i) – either of these effects may be of interest to us.

- Total intracranial volume (TIV) integrates GM, WM and CSF, or attempts to measure the skull-volume directly
  - Can still identify global brain shrinkage (skull is fixed!)
  - Can give more powerful and/or more interpretable results
  - See also Pell et al (2009) doi:10.1016/j.neuroimage.2008.02.050

#### Some Explanations of the Differences

### **Selected References**

#### Overview

- Voxel-Based Morphometry
- Tissue Segmentation
  - Gaussian mixture model
  - Intensity non-uniformity correction
  - Deformed tissue probability maps
- Diffeomorphic Registration
- Longitudinal Registration
- Multivariate Shape Models

## Segmentation

- Segmentation in SPM8 also estimates a spatial transformation that can be used for spatially normalising images.
  - It uses a generative model, which involves:
    - Mixture of Gaussians (MOG)
    - Bias Correction Component
    - Warping (Non-linear Registration) Component

### Mixture of Gaussians (MOG)

 Classification is based on a Mixture of Gaussians model (MOG), which represents the intensity probability density by a number of Gaussian distributions.

Image Intensity ——

### **Belonging Probabilities**

Belonging probabilities are assigned by normalising to one.

#### Modelling a Bias Field

**Corrupted image** 

**Bias Field** 

**Corrected image** 

# **Tissue Probability Maps**

Includes additional non-brain tissue classes (bone, and soft tissue)

×0 (

#### Deforming the Tissue Probability Maps

 Tissue probability images are deformed so that they can be overlaid on top of the image to segment.

# Multi-spectral

#### Limitations of the current model

- Assumes that the brain consists of only the tissues modelled by the TPMs
  - No spatial knowledge of lesions (stroke, tumours, etc)
- Prior probability model is based on healthy brains (IXI dataset from London).
  - Less accurate for subjects outside this population
- Needs reasonable quality images to work with
  - No severe artefacts
  - Good separation of intensities
  - Reasonable initial alignment with TPMs.

## Overview

- Morphometry
- Voxel-Based Morphometry
- Tissue Segmentation
- Diffeomorphic Registration
  - Compositions
  - Objective function
  - Template creation
- Longitudinal Registration
  - Multivariate Shape Models

#### **Diffeomorphic Deformations**

## Composition

#### Small Deformation Approximation

The composition:

φ°θ

Would be approximated with:

```
\mathsf{Id} + ((\vartheta \mathsf{-}\mathsf{Id}) + (\varphi \mathsf{-}\mathsf{Id}))
```

The inversion:

φ<sup>-1</sup>

Would be approximated with:

Id -(φ-Id)

Not good approximations for large deformations.

## **Diffeomorphic Image Registration**

- Minimises two terms:
- 1. A measure of distance between images
- 2. A measure of the amount of distortion.

Because we can not simply add displacement fields, large deformations are generated by composing many small deformations.

The amount of distortion is computed by summing up the distortion measures from the small displacements.

#### Effect of Different Distortion Measures

#### Two diffeomorphic approaches in SPM

#### Dartel.

- Uses the same small deformation composed multiple times.
- Faster than Geodesic Shooting.
- Gives similar deformations to Geodesic Shooting.
- Currently more additional utilities.

#### **Geodesic Shooting**

- Uses the optimal series of small deformations, which are composed together.
- More mathematically correct than Dartel.
- Gives nicer maps of volume change than Dartel.
- Likely to replace Dartel in future.

#### In case anyone asks for equations

#### Dartel

$$E = \frac{1}{2} || Lv ||^{2} dt + \frac{1}{2\sigma^{2}} || I_{0} \circ \varphi_{1}^{-1} - I_{1} ||^{2}$$

#### **Geodesic Shooting**

$$E = \frac{1}{2} || Lv_0 ||^2 dt + \frac{1}{2\sigma^2} || I_0 \circ \varphi_1^{-1} - I_1 ||^2$$

$$\varphi_0 = id$$
$$\dot{\varphi} = \mathbf{V} \circ \varphi_t$$

$$\varphi_0 = Id$$
  

$$\dot{\varphi} = V_t \circ \varphi_t$$
  

$$V_t = K(|d\varphi_t^{-1}| (d\varphi_t^{-1})^T ((L^*LV_0) \circ \varphi_t^{-1}))$$

equivalent solution to this variational problem:

$$E = \frac{1}{2} \int_{t=0}^{1} ||Lv_t||^2 dt + \frac{1}{2\sigma^2} ||I_0 \circ \varphi_1^{-1} - I_1||^2$$

$$\varphi_0 = id$$
$$\dot{\varphi} = V_t \circ \varphi_t$$

  - Multivariate Shape Models
    - Multivariate nature of shape
    - "Scalar momentum"
    - Some evaluations

# Multivariate shape models

- In theory, assumptions about structural covariance among brain regions are more biologically plausible. Form determined (in part) by spatio-temporal modes of gene expression.
- Empirical evidence in (eg) Mechelli, Friston, Frackowiak & Price. Structural covariance in the human cortex. Journal of Neuroscience 25(36):8303-8310 (2005).
- We should work with the most accurate modelling assumptions available.
  - If a model is accurate, it will make accurate predictions.

# Argument from authority I

"The morphologist, when comparing one organism with another, describes the differences between them point by point, and "character" by "character". If he is from time to time constrained to admit the existence of "correlation" between characters, yet all the while he recognises this fact of correlation somewhat vaguely, as a phenomenon due to causes which, except in rare instances, he cannot hope to trace ; and he falls readily into the habit of thinking and talking of evolution as though it had proceeded on the lines of his own descriptions, point by point, and character by character."

D'Arcy Thompson (Growth and Form, 1917).

# Argument from authority II

"This unhappy result can be traced to the piecemeal tests which have hitherto been used. A bone or a tooth is a unit ; it is not a discrete assembly of independent measurements."

Jacob Bronowski & W.M. Long (Nature, 1951).

"The right statistical method must treat the set of variates as a single coherent matrix ; and this is, in fact, the technique of multivariate analysis."

Jacob Bronowski & W.M. Long (Nature, 1951).

## Some 2D Shapes

# Fisher's Linear Discriminant Analysis

- A multivariate model.
- Special case of canonical variates analysis.
- A generative model.

![](_page_70_Figure_4.jpeg)

![](_page_70_Figure_5.jpeg)

# Other linear discrimination approaches

-1

- Can also use discriminative models.
- Anatomical differences are encoded by the vector orthogonal to the separating hyper-plane.
- The most accurate model of difference is the one that best separates the groups.

![](_page_71_Figure_4.jpeg)

Ground truth

# Regression

#### For predicting a continuous variable

### Weight Map

For linear classifiers, predictions are made by:

$$y = a_1 \times x_1 + a_2 \times x_2 + a_3 \times x_3 + \dots + b$$

where: *y* is the prediction

 $x_1$ ,  $x_2$ ,  $x_3$  etc are voxels in the image to classify  $a_1$ ,  $a_2$ ,  $a_3$  etc are voxels in a weight map *b* is a constant offset.

The weight map can be visualised

## Maps

#### Multivariate weight map

#### **Simple T statistic image**

Prettier – but does not accurately characterise the effects of age.

# "Scalar Momentum"

For diffeomorphic registration by least-squares matching, the warps ( $\varphi$ ) are encoded by an initial velocity (v(0)):

# The 2D shapes (again)

## "Scalar momentum" $|\det d\varphi|(I_0 - I_1 \circ \varphi)$

## The 2D shapes (yet again)
