

Variance Component Estimation a.k.a. Non-Sphericity Correction

Overview

- Variance-Covariance Matrix
- What is (and isn't) sphericity?
- Why is non-sphericity a problem?
- How do proper statisticians solve it?
- How did SPM99 solve it.
- How does SPM2 solve it?
- What is all the fuss?
- Some 2nd level examples.

Variance-Covariance matrix

Length of Swedish men

Weight of Swedish men

$\mu=180\text{cm}, \sigma=14\text{cm} (\sigma^2=200)$

$\mu=80\text{kg}, \sigma=14\text{kg} (\sigma^2=200)$

Each completely characterised by μ (mean) and σ^2 (variance),
i.e. we can calculate $p(l|\mu, \sigma^2)$ for any l

Variance-Covariance matrix

- Now let us view length and weight as a 2-dimensional stochastic variable $p(l,w)$.

$$\mu = \begin{bmatrix} 180 \\ 80 \end{bmatrix} \quad \Sigma = \begin{bmatrix} 200 & 100 \\ 100 & 200 \end{bmatrix} \quad p(l,w|\mu, \Sigma)$$

What is (and isn't) sphericity?

Sphericity $\leftrightarrow iid \leftrightarrow N(\mu, \Sigma = \sigma^2 \mathbf{I})$

$$\Sigma = \begin{bmatrix} \sigma^2 & 0 \\ 0 & \sigma^2 \end{bmatrix}$$

Variance quiz

Variance quiz

Variance quiz

Variance quiz

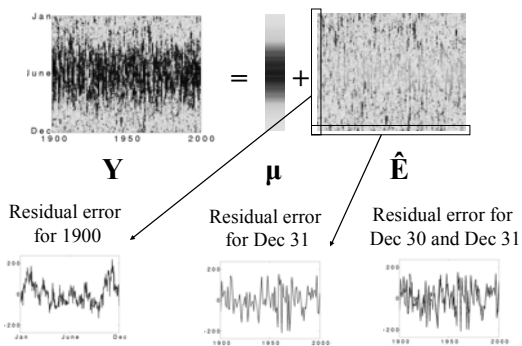

Example:

”The rain in Norway stays mainly in Bergen”
or
”A hundred years of gloominess”

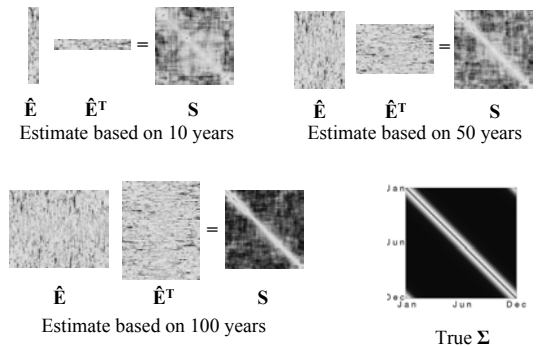

The rain in Bergen continued

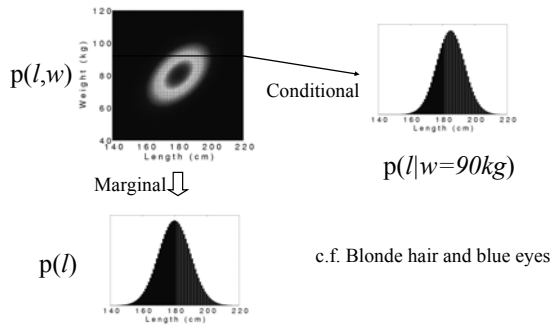

The rain in Bergen

The rain in Bergen concluded

Why is non-sphericity a problem?

How do "proper" statisticians solve it? (they cheat)

- Greenhouse-Geisser (Satterthwaite) correction.
- Correction factor $(n-1)^{-1} \leq \epsilon \leq 1$

More Greenhouse-Geisser

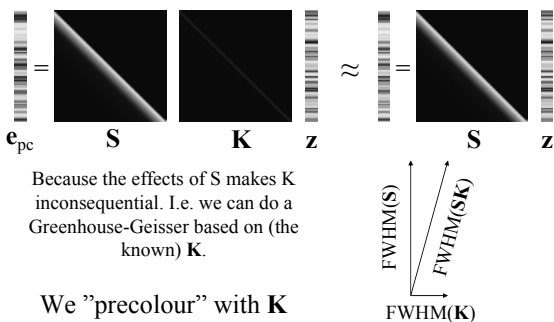

How was it solved in SPM99?

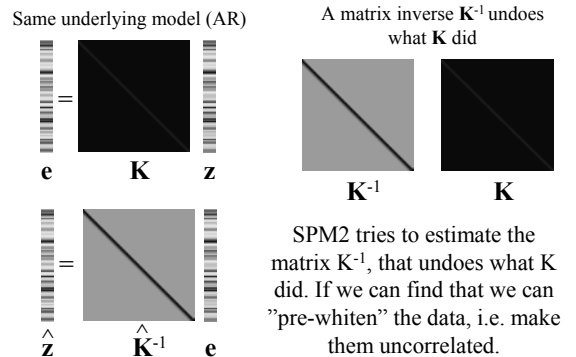

- Remember, If we know Σ we can correct df .

Why on earth would we do that??

Hope SPM2 is a bit more clever than that.

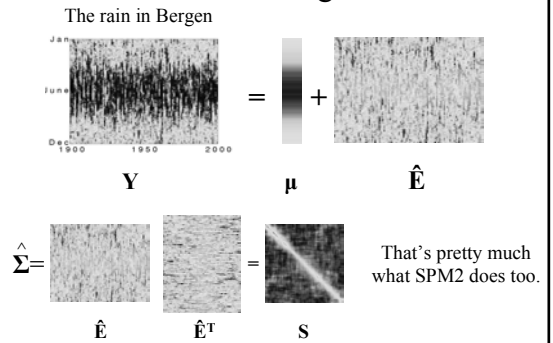

Well, how on earth can we do that?

$$E\{zz^T\} = E\left\{ \begin{matrix} \text{[column vector]} \\ \text{[row vector]} \end{matrix} \right\} = \sigma^2 \mathbf{I} = \text{[diagonal matrix]}$$

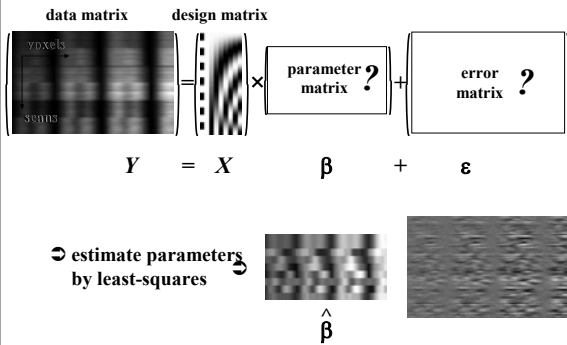

$$\Sigma = E\{ee^T\} = E\{Kzz^TK^T\} = \sigma^2 KK^T = \text{[diagonal matrix]}$$

I.e. K is the matrix root of Σ , so all we need to do is estimate it.

Remember how we estimated Σ for the rain in Bergen?

Matrix model...

Restricted Maximum Likelihood

Maximum Likelihood

- If we have a model and know it's parameters we can calculate the likelihood (sort of) of any data point.

$$y_i = \mu + e_i, \quad e_i \sim N(0, \sigma^2) \Rightarrow p(y_i | \mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(y_i - \mu)^2}{2\sigma^2}}$$

Maximum Likelihood

- If we have a model and know it's parameters we can calculate the likelihood (sort of) of any data point.

$$y_i = \mu + e_i, \quad e_i \sim N(0, \sigma^2) \Rightarrow p(y_i | \mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(y_i - \mu)^2}{2\sigma^2}}$$

Maximum Likelihood

- If we have a model and know it's parameters we can calculate the likelihood (sort of) of any data point.

$$y_i = \mu + e_i, \quad e_i \sim N(0, \sigma^2) \quad \Rightarrow \quad p(y_i | \mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(y_i - \mu)^2}{2\sigma^2}}$$

a.k.a

Maximum Likelihood

- And we can calculate the likelihood of the entire data vector.

$$p(\mathbf{y} | \mu, \sigma^2) = \prod_{i=1}^n \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(y_i - \mu)^2}{2\sigma^2}}$$

But, does that really make us any happier?

- In reality we don't know the parameters of our model. They are what we want to estimate.

But, does that really make us any happier?

- So, let us try some other values for the parameters.

But, does that really make us any happier? (Yeah!)

- Let us say we have a more complicated model

$$e.g. \quad p(\mathbf{y} | \beta, \Sigma(\lambda)) = \frac{1}{(2\pi)^n |\Sigma|^{\frac{1}{2}}} e^{-\frac{1}{2}(\mathbf{y} - \mathbf{X}\beta)^T \Sigma^{-1} (\mathbf{y} - \mathbf{X}\beta)}$$

where $\Sigma(\lambda) = \lambda_1 \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + \lambda_2 \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$ (Rather typical first level fMRI model)

- We still have our data (\mathbf{y})
- We can still calculate the likelihood for each choice of $\beta = [\beta_1, \beta_2, \dots]$ and $\lambda = [\lambda_1, \lambda_2]$.
- And, of course, we can still choose those that maximise the likelihood.

What is all the fuss then?

- Did you ever wonder about the (n-1) when estimating sample variance?

What is all the fuss then?

- Did you ever wonder about the $(n-1)$ when estimating sample variance?

What is all the fuss then?

- Did you ever wonder about the $(n-1)$ when estimating sample variance?

What is all the fuss then?

- Did you ever wonder about the $(n-1)$ when estimating sample variance?

etc...

Or seen slightly differently

- Data (20 points) drawn from an $N(5,1)$ distribution.

Likelihood as function of μ and σ^2

μ and σ^2 at the location of the peak is the ML-estimate

And seen as an image

N.B. location of max for σ^2 depends on estimate of μ

Or seen slightly differently

- Data (20 points) drawn from an $N(5,1)$ distribution.

Likelihood as function of μ and σ^2

μ and σ^2 at the location of the peak is the ML-estimate

And seen as an image

σ^2 max as function of μ

Unbiased estimate

ML-estimate

And the same for estimating serial correlations (c.f. Durbin-Watson)

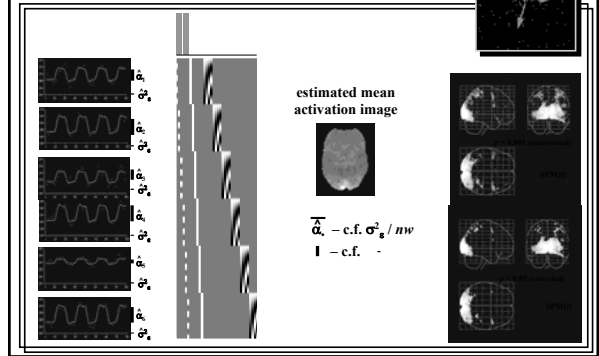

Hur man än vänder sig är rumpan bak

True variance-covariance matrix	Sample variance-covariance matrix	Effects of error in parameter estimates
$\Sigma = E\{\mathbf{e}\mathbf{e}^T\}$	$= E\{\hat{\mathbf{e}}\hat{\mathbf{e}}^T\}$	$+ \mathbf{X}\text{Cov}(\beta)\mathbf{X}^T$
This is what we want	This is what we observe	This we can calculate if...

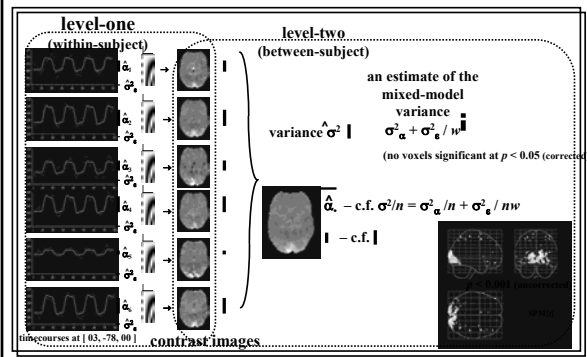

...we know this. Bummer!

ReML/EM

Multi-subject analysis...

...random effects

Non-sphericity for 2nd level models

- Errors are independent but not identical
- Errors are not independent and not identical

Non-Sphericity

Error can be Independent but Non-Identical when...

- 1) One parameter but from different groups
e.g. patients and control groups
- 2) One parameter but design matrices differ across subjects
e.g. subsequent memory effect

Non-Sphericity

Error can be Non-Independent and Non-Identical when...

- 1) Several parameters per subject
e.g. Repeated Measurement design
- 2) Conjunction over several parameters
e.g. Common brain activity for different cognitive processes
- 3) Complete characterization of the hemodynamic response
e.g. F-test combining HRF, temporal derivative and dispersion regressors

Example 1

U. Noppeney et al.

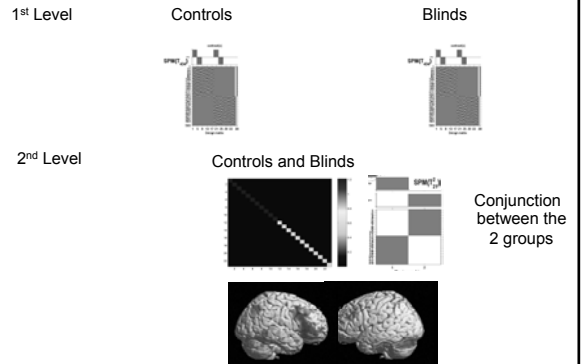

Stimuli: Auditory Presentation (SOA = 4 secs) of
(i) words and (ii) words spoken backwards

Subjects: (i) 12 control subjects
(ii) 11 blind subjects

Scanning: fMRI, 250 scans per subject, block design

Q. What are the regions that activate for real words relative to reverse words in **both** blind and control groups?

Independent but Non-Identical Error

Example 2

U. Noppeney et al.

Stimuli: Auditory Presentation (SOA = 4 secs) of words

motion	sound	visual	action
"jump"	"click"	"pink"	"turn"

• Subjects: (i) 12 control subjects

• Scanning: fMRI, 250 scans per subject, block design

Q. What regions are affected by the semantic content of the words?

Non-Independent and Non-Identical Error
