

Topological Inference

Guillaume Flandin

Wellcome Trust Centre for Neuroimaging
University College London

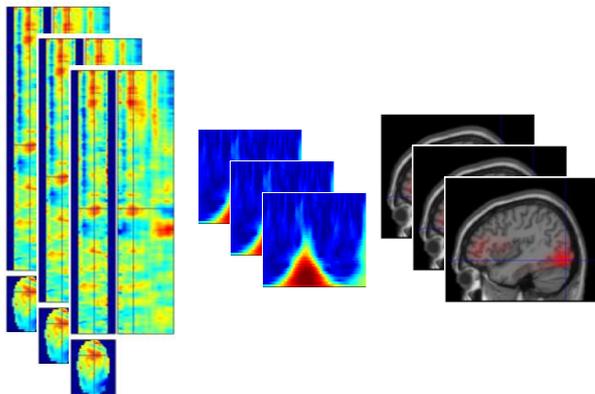

$$y = \begin{bmatrix} \blacksquare & \blacktriangleleft \\ \blacktriangleright & \square \end{bmatrix} \beta + \varepsilon$$

Pre-
processings

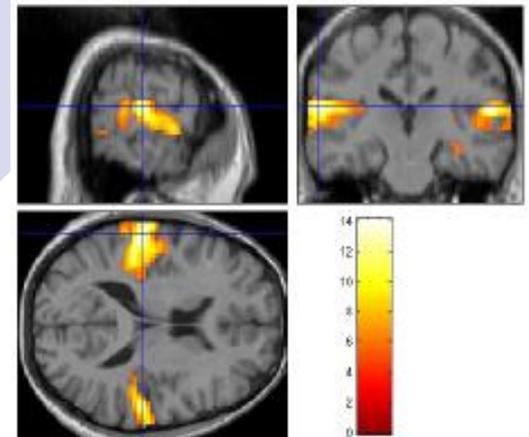

General
Linear
Model

Statistical
Inference

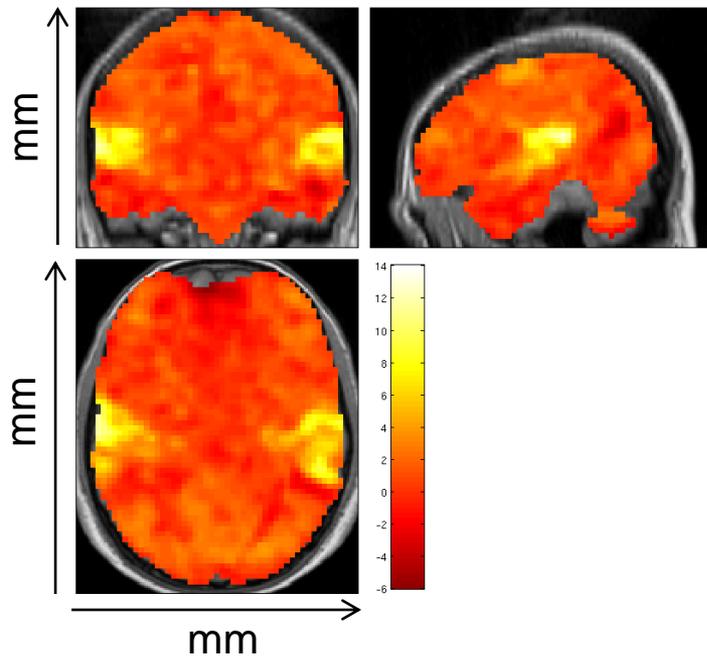

$$\hat{\beta} = (X^T X)^{-1} X^T y$$

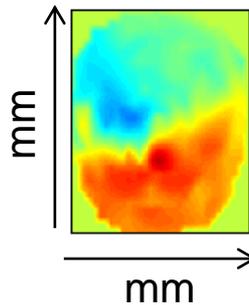

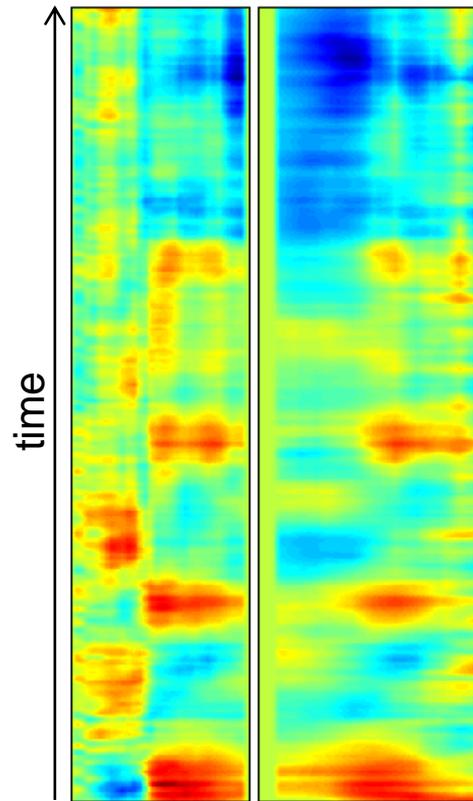

$$\hat{\sigma}^2 = \frac{\hat{\varepsilon}^T \hat{\varepsilon}}{\text{rank}(X)}$$

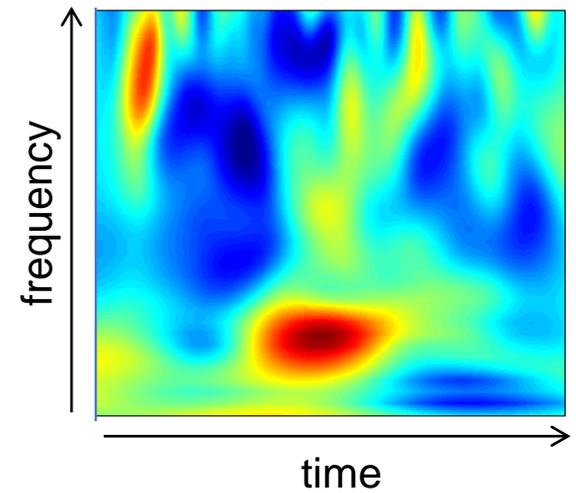

Statistical Parametric Maps

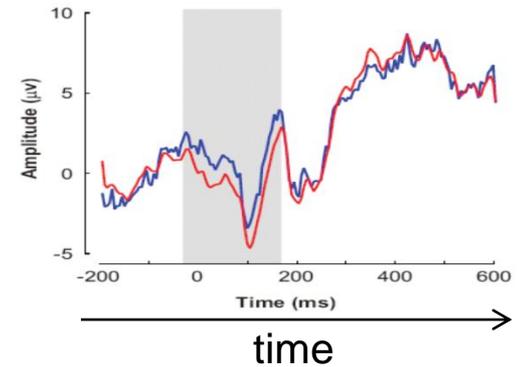

3D M/EEG source reconstruction, fMRI, VBM

2D+t scalp-time

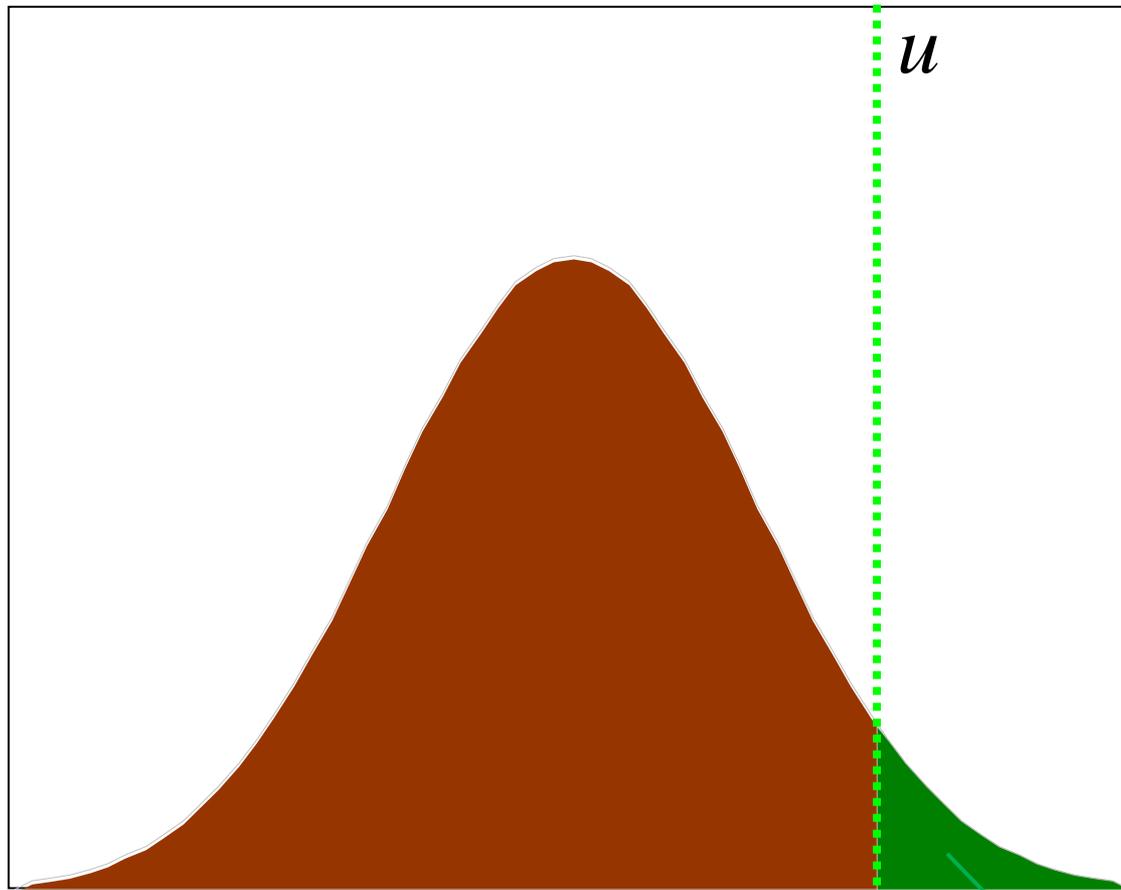

2D time-frequency

1D time

Single test

Null distribution of test statistic T

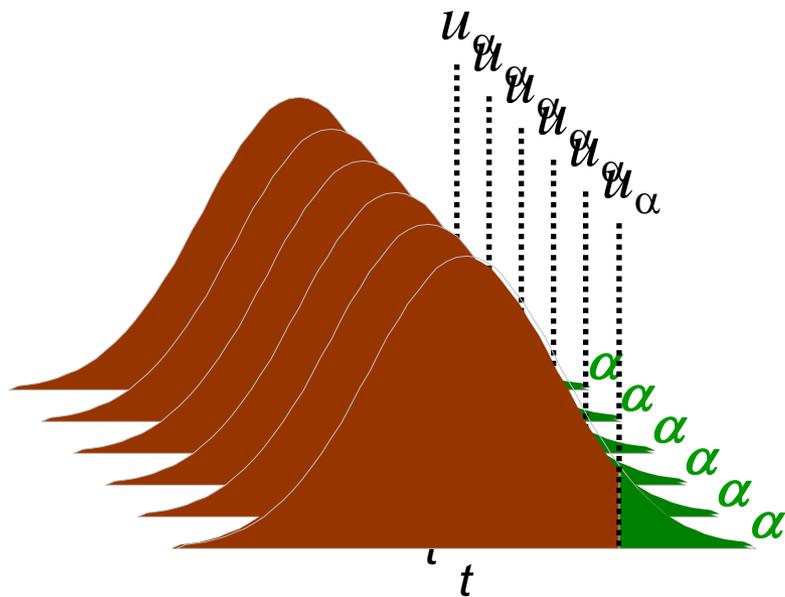

Null Hypothesis H_0 :
zero activation

Decision rule (threshold) u :
determines false positive
rate α

\Rightarrow Choose u to give acceptable
 α under H_0

$$\alpha = p(t > u | H_0)$$

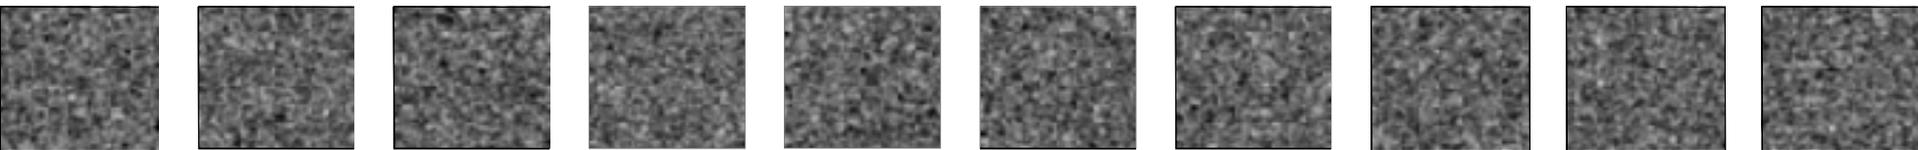

Multiple tests

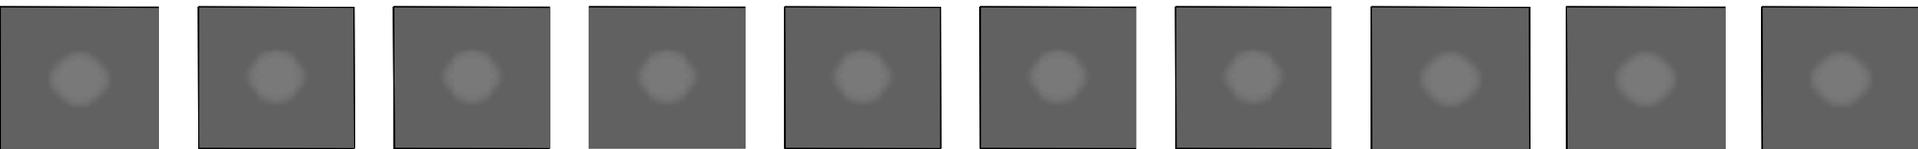

If we have 100,000 voxels,
 $\alpha=0.05 \Rightarrow 5,000$ false positive voxels.

This is clearly undesirable.

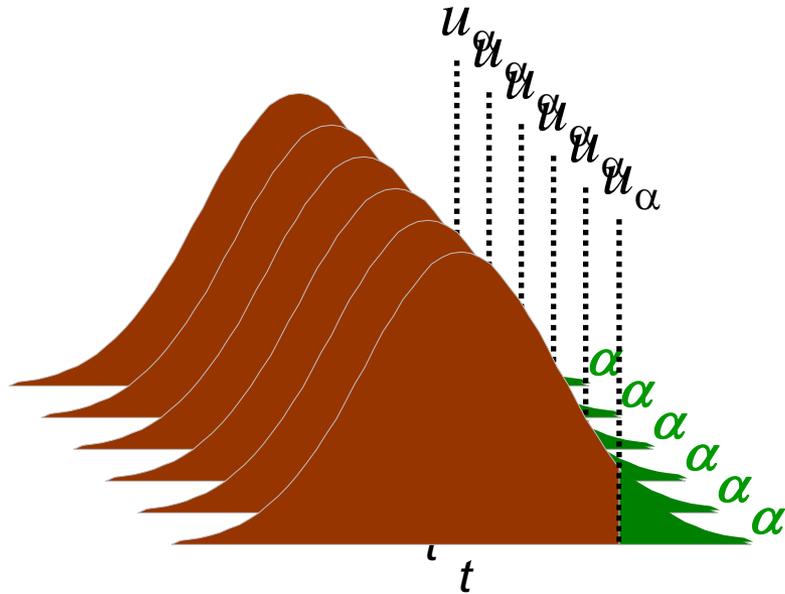

Noise

Signal

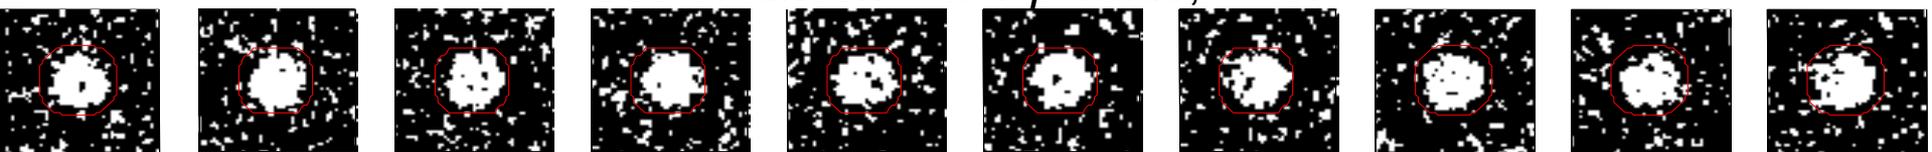

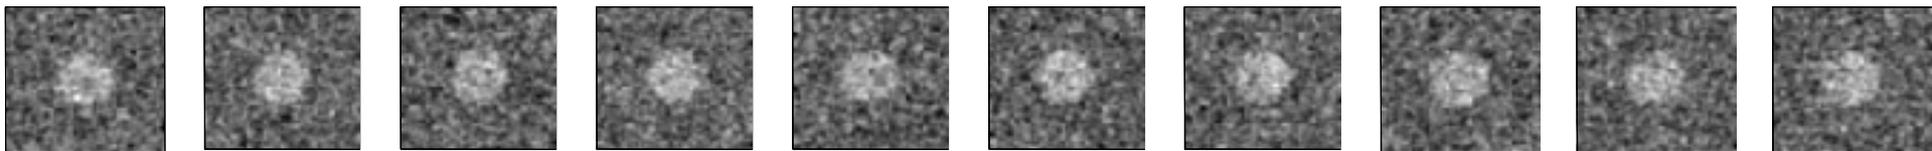

Multiple tests

If we have 100,000 voxels,
 $\alpha=0.05 \Rightarrow 5,000$ false positive voxels.

This is clearly undesirable.

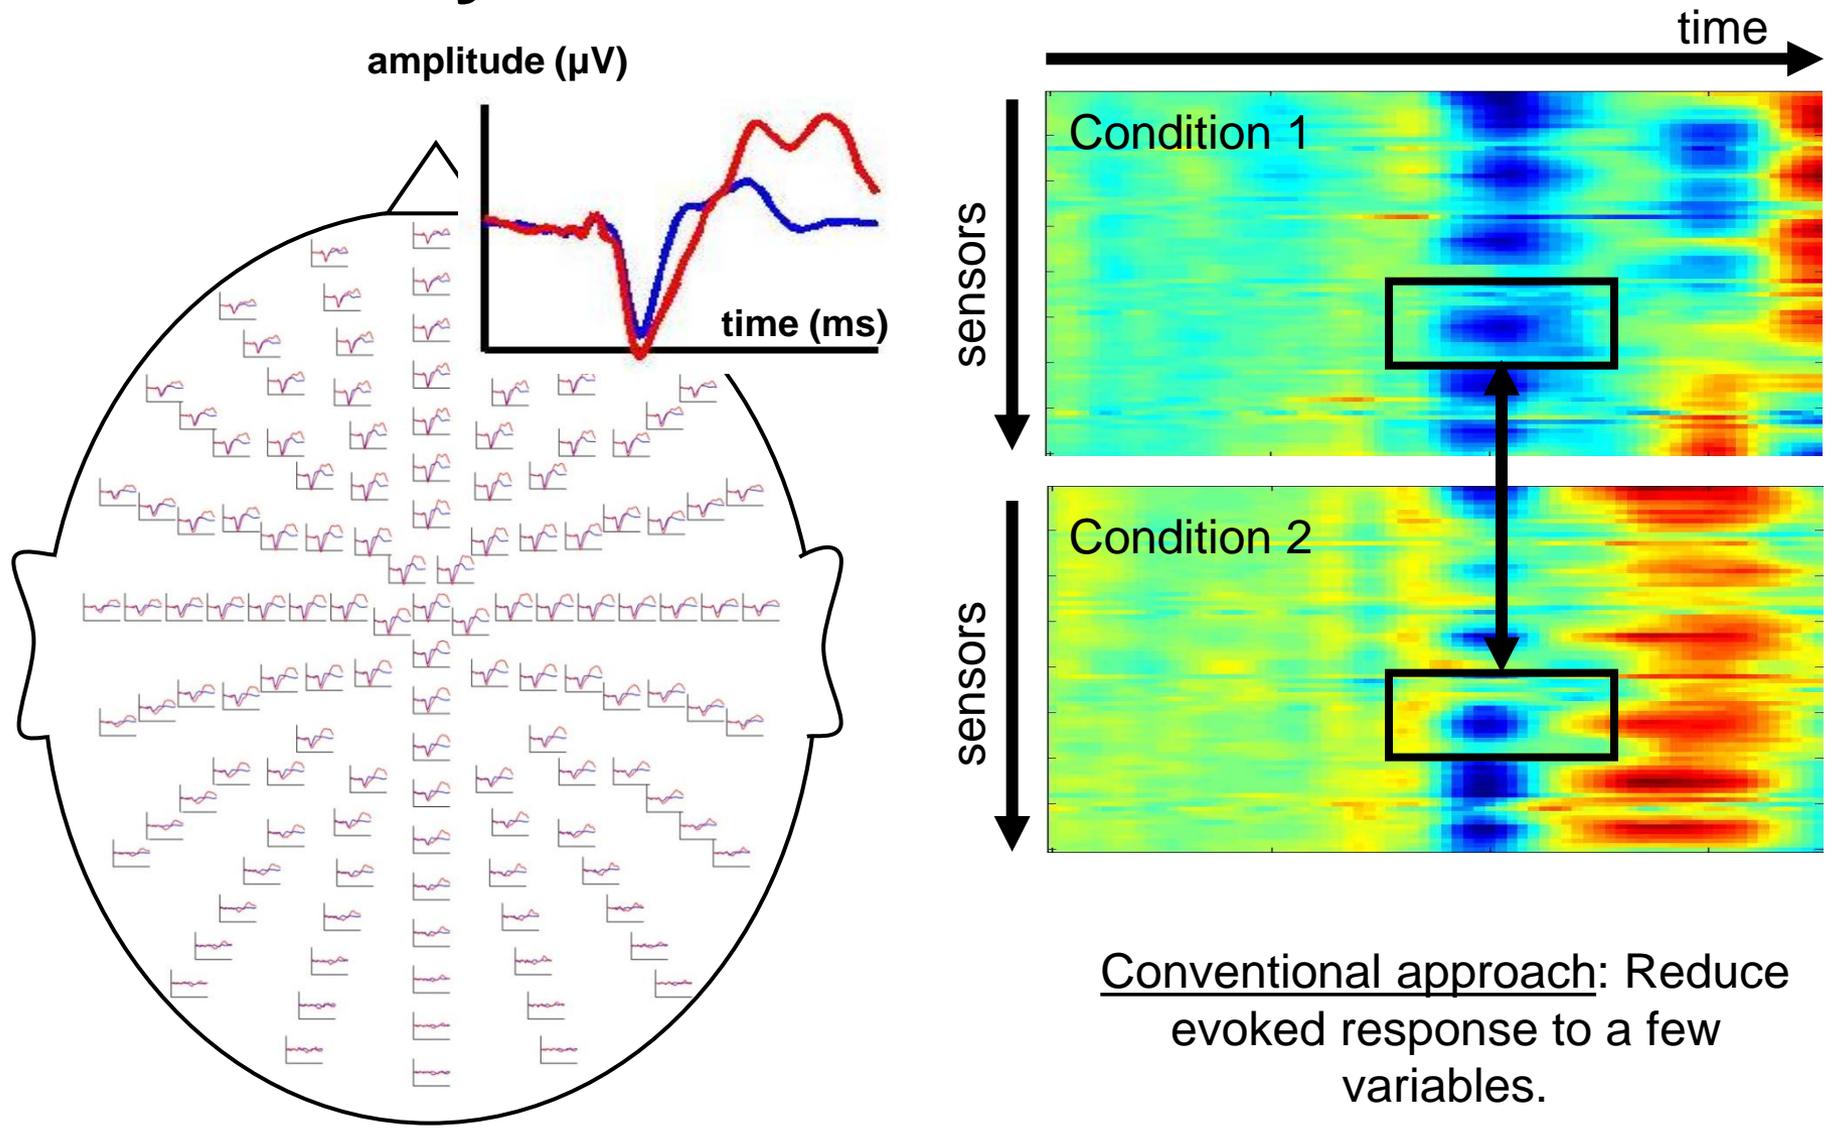

Use of 'uncorrected' p -value, $\alpha = 0.1$

11.3% 11.3% 12.5% 10.8% 11.5% 10.0% 10.7% 11.2% 10.2% 9.5%

Percentage of Null Pixels that are False Positives

M/EEG analysis at sensor level

Conventional approach: Reduce evoked response to a few variables.

Family-Wise Null Hypothesis

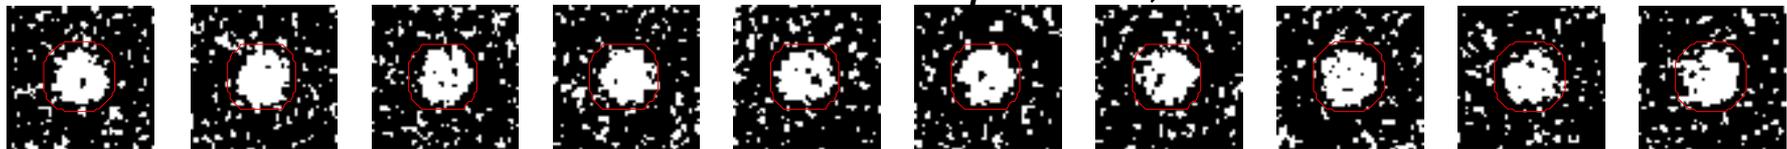

Family-Wise Null Hypothesis:
Activation is zero everywhere

If we reject a voxel null hypothesis at *any* voxel,
 we reject the family-wise Null hypothesis

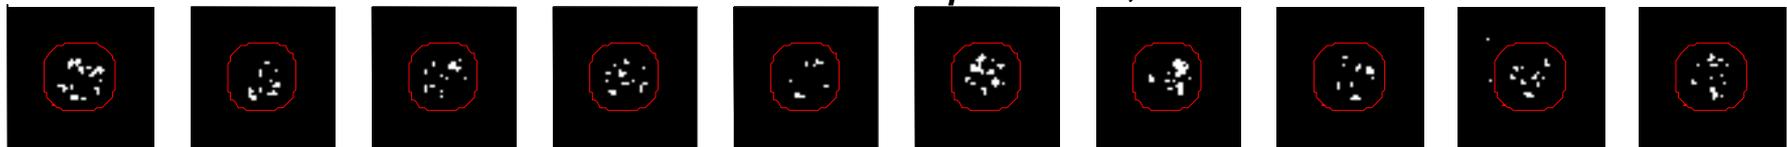

A FP *anywhere* in the image gives a **Family Wise Error** (FWE)

Family-Wise Error rate (FWER) = 'corrected' p -value

Use of 'uncorrected' p -value, $\alpha = 0.1$

Use of 'corrected' p -value, $\alpha = 0.1$

FWE

Bonferroni correction

The Family-Wise Error rate (FWER), α_{FWE} , for a family of N tests follows the inequality:

$$\alpha_{FWE} \leq N\alpha$$

where α is the test-wise error rate.

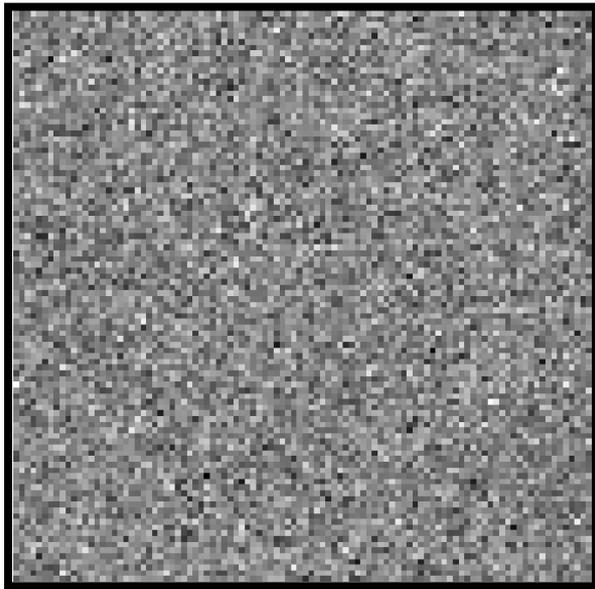

Therefore, to ensure a particular FWER choose:

$$\alpha = \frac{\alpha_{FWE}}{N}$$

This correction does not require the tests to be independent but becomes very stringent if dependence.

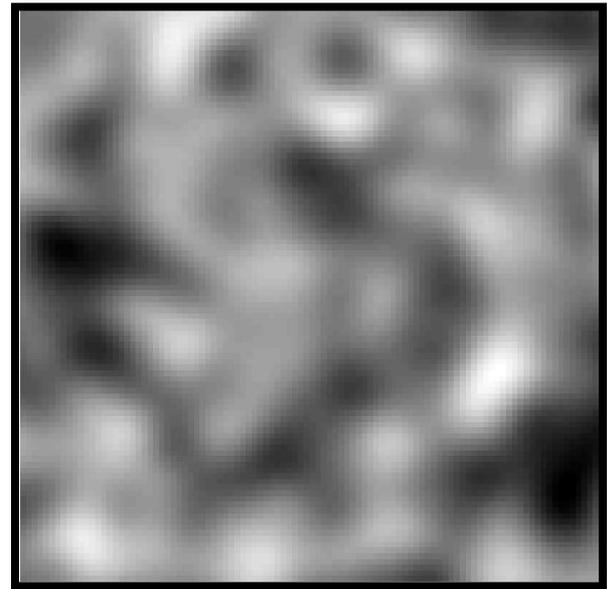

Spatial correlations

100 x 100 independent tests

Discrete data

Spatially correlated tests (FWHM=10)

Spatially extended data

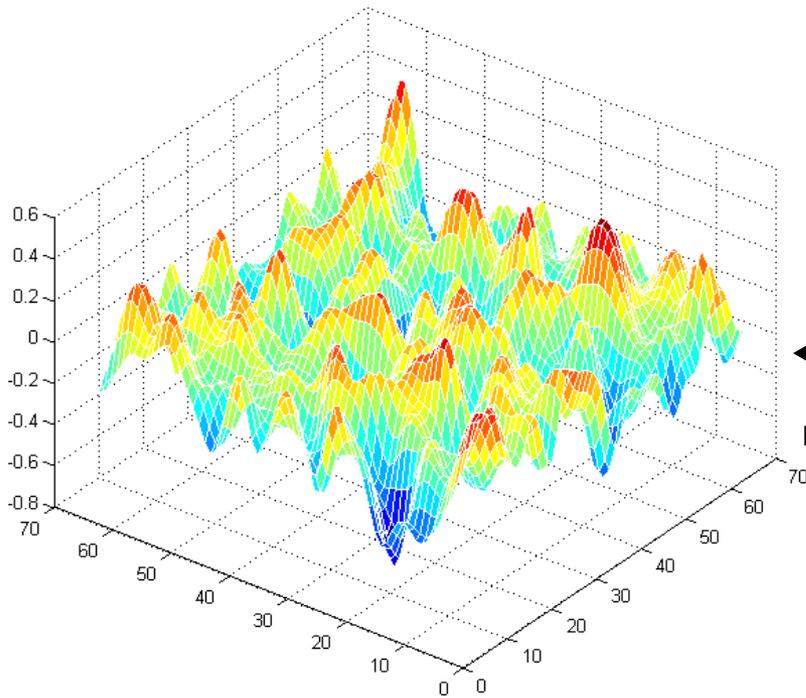

Bonferroni is too conservative for spatial correlated data.

$$10,000 \text{ voxels} \Rightarrow \alpha_{BONF} = \frac{0.05}{10,000} \Rightarrow u_c = 4.42 \quad (\text{uncorrected } u = 1.64)$$

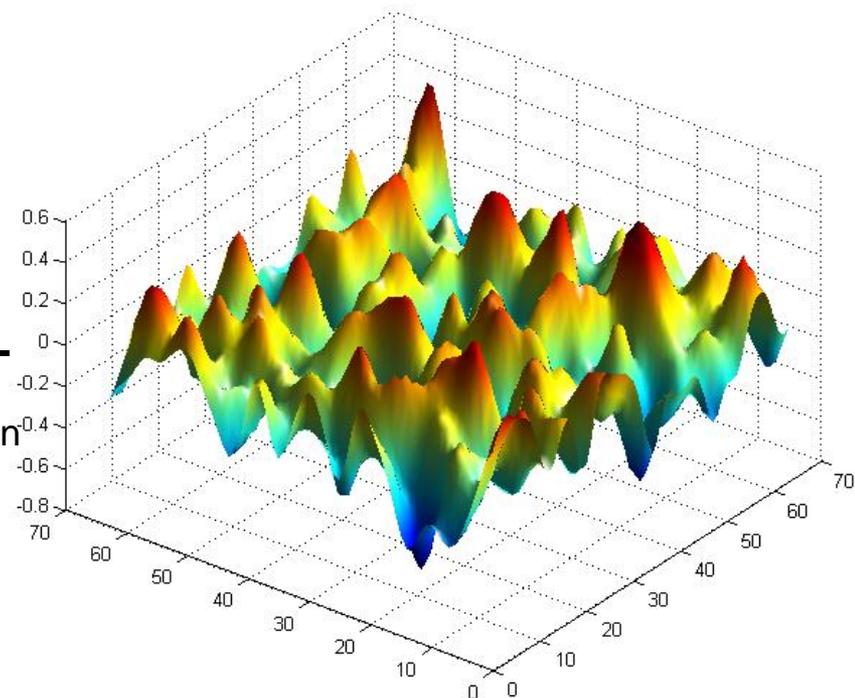

Random Field Theory

⇒ Consider a statistic image as a discretisation of a continuous underlying random field.

⇒ Use results from continuous **random field theory**.

lattice
representation

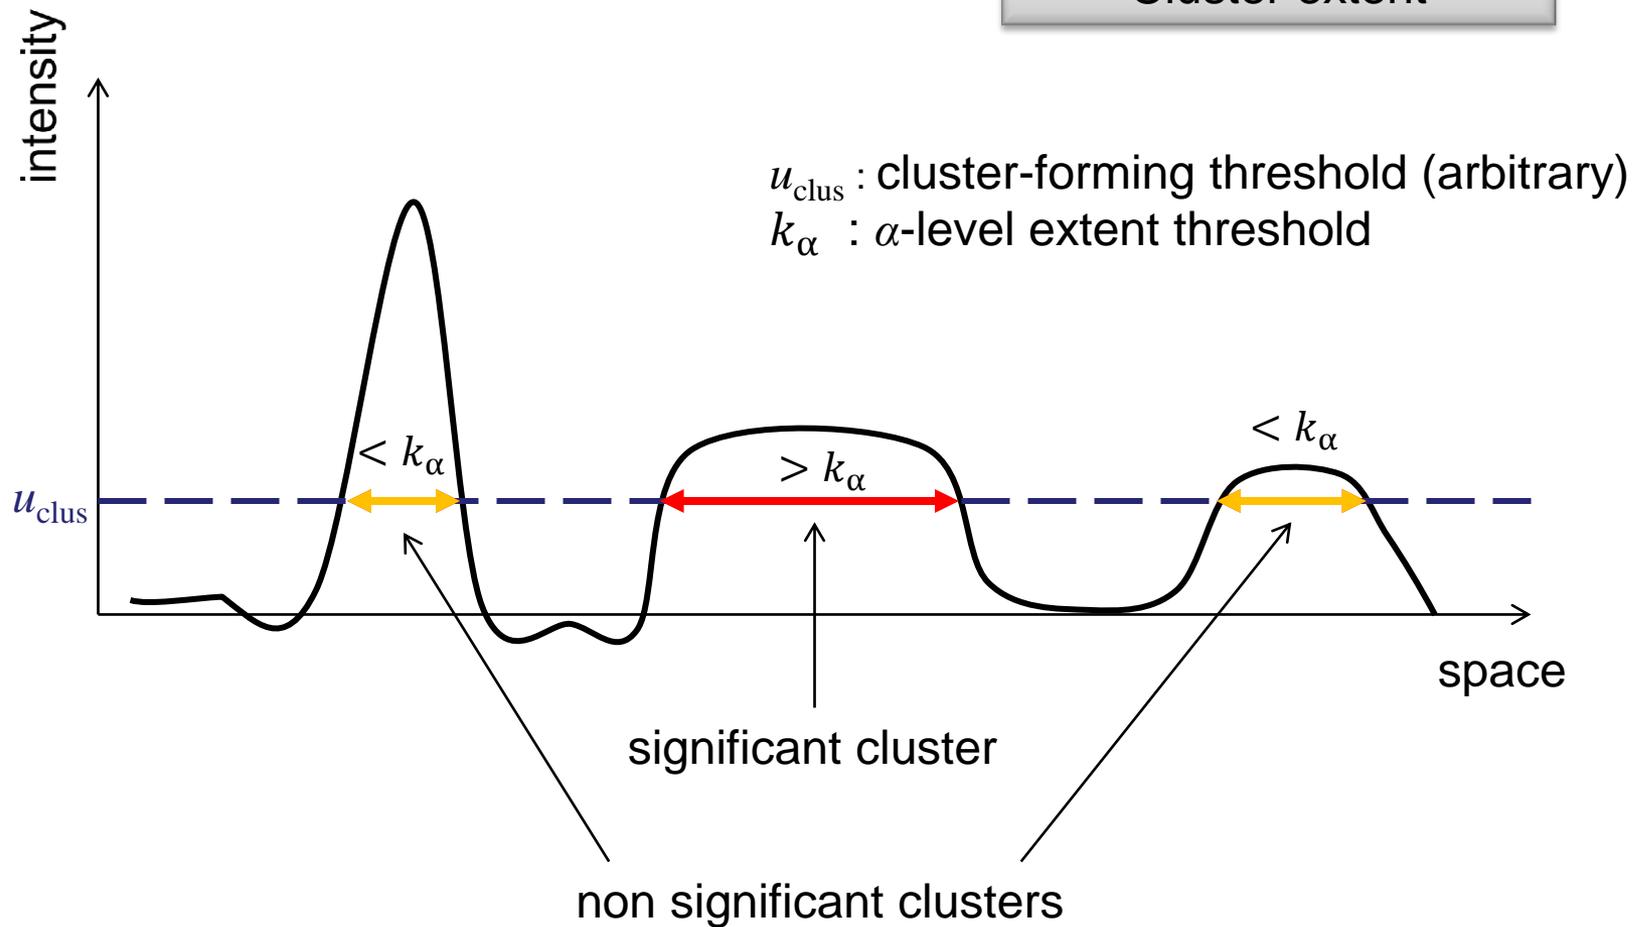

Topological inference

Topological feature:
Peak height

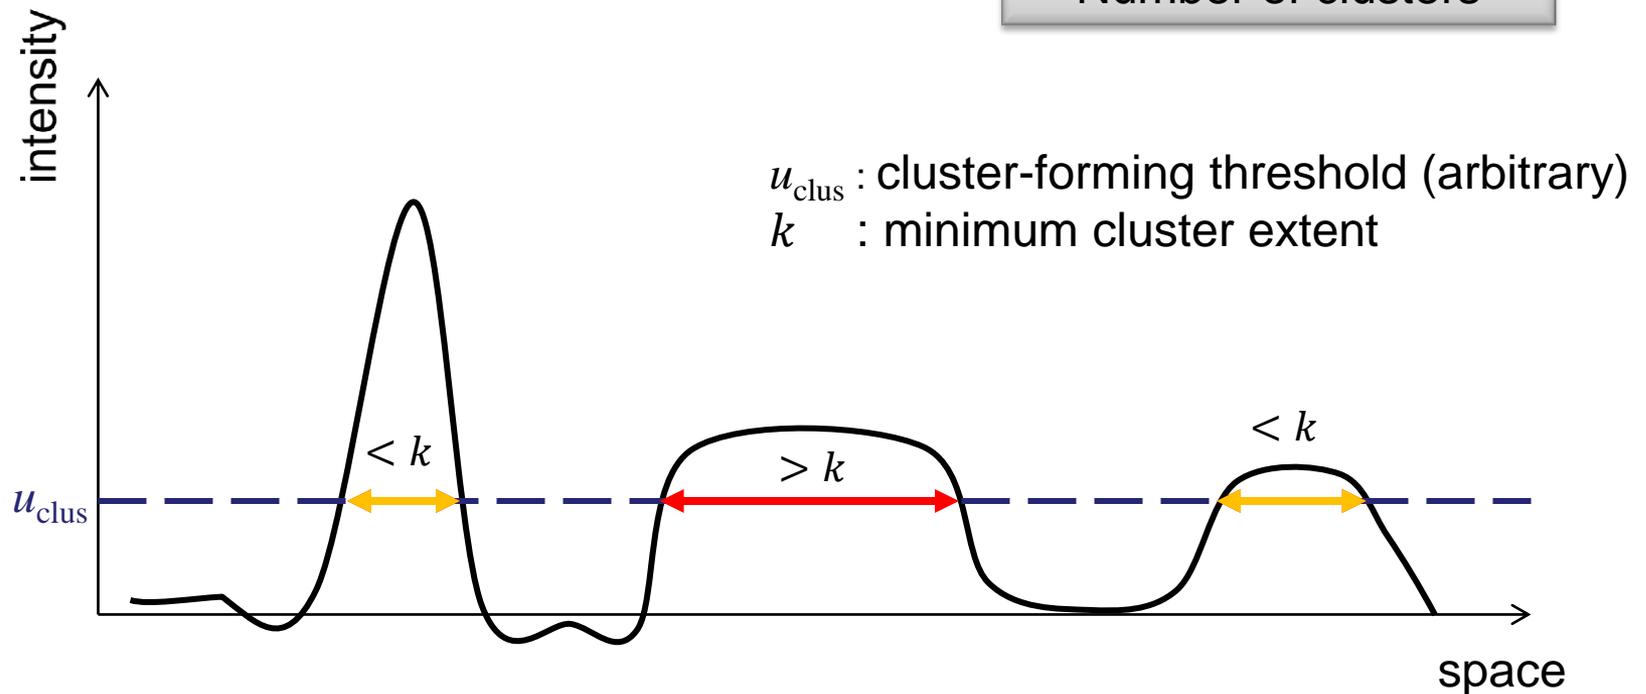

Topological inference

Topological feature:
Cluster extent

Topological inference

Topological feature:
Number of clusters

Here, $c=1$, only one cluster larger than k .

Euler Characteristic χ

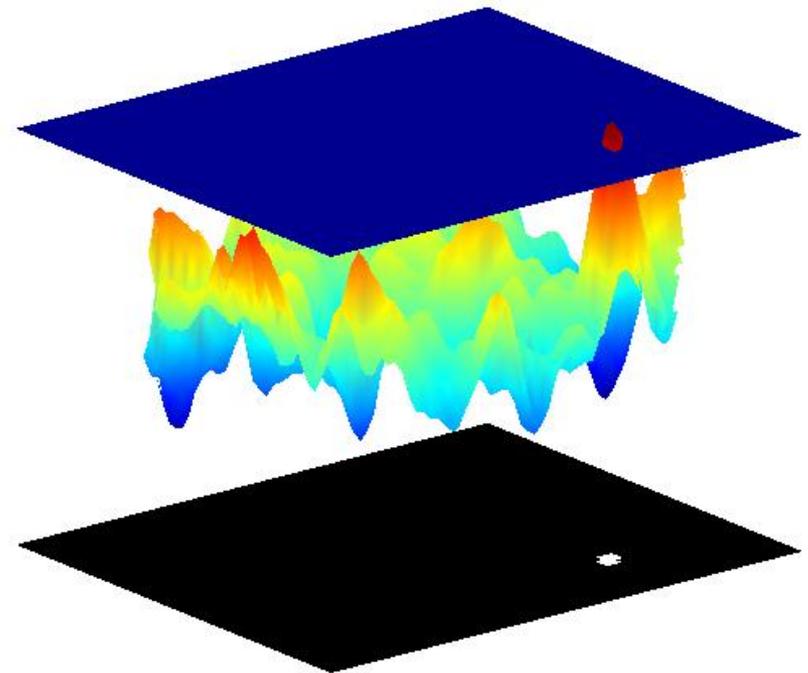

Euler Characteristic χ_u :

- Topological measure

$$\chi_u = \# \text{ blobs} - \# \text{ holes}$$

- at high threshold u :

$$\chi_u = \# \text{ blobs}$$

$$FWER = p(FWE)$$

$$= p(\text{one or more blobs} | H_0)$$

No holes

Zero or
one blob

$$\approx p(\chi_u \geq 1 | H_0)$$

$$\approx E[\chi_u | H_0] \approx \alpha_{FWE}$$

Expected Euler Characteristic

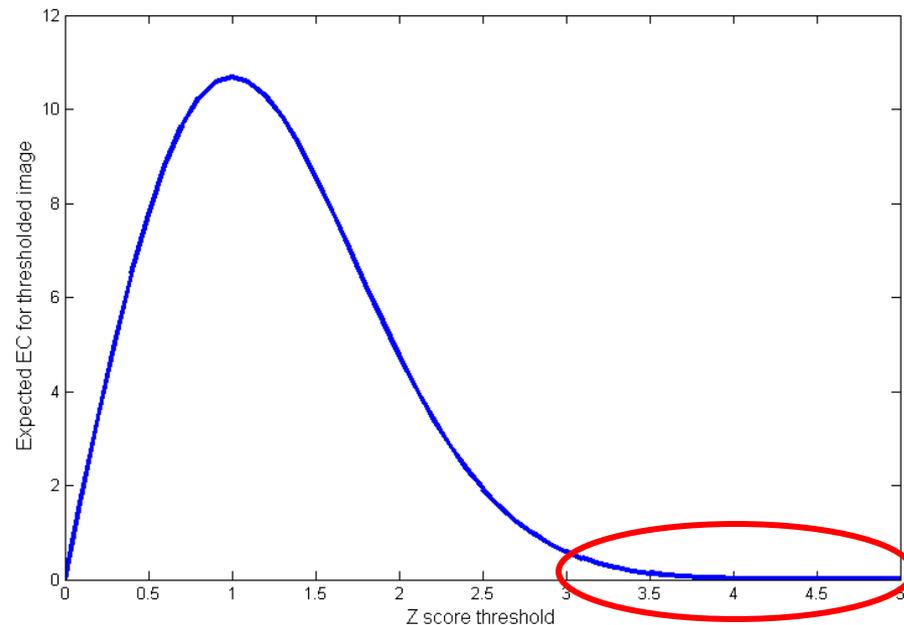

$$E[\chi_u] = \lambda(\Omega) |\Lambda|^{1/2} u \exp(-u^2/2) / (2\pi)^{3/2}$$

2D Gaussian Random Field

- Ω : search region
- $\lambda(\Omega)$: volume
- $|\Lambda|^{1/2}$: roughness (1 / smoothness)

100 x 100 Gaussian Random Field
with FWHM=10 smoothing

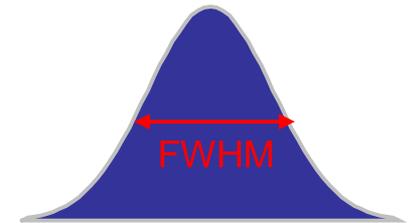

$\alpha_{FWE} = 0.05 \Rightarrow u_{RFT} = 3.8$
($u_{BONF} = 4.42$, $u_{uncorr} = 1.64$)

Smoothness

Smoothness parameterised in terms of FWHM:

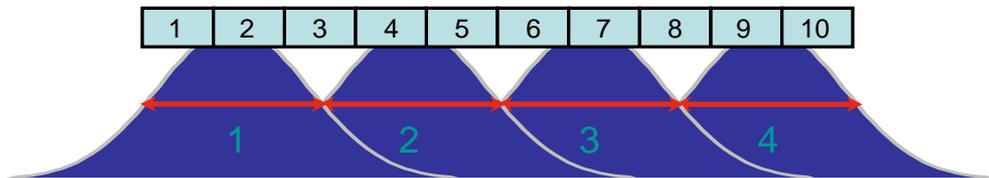

Size of Gaussian kernel required to smooth i.i.d. noise to have same smoothness as observed null (standardized) data.

RESELS (Resolution Elements):

$$1 \text{ RESEL} = FWHM_x FWHM_y FWHM_z$$

RESEL Count R = volume of search region in units of smoothness

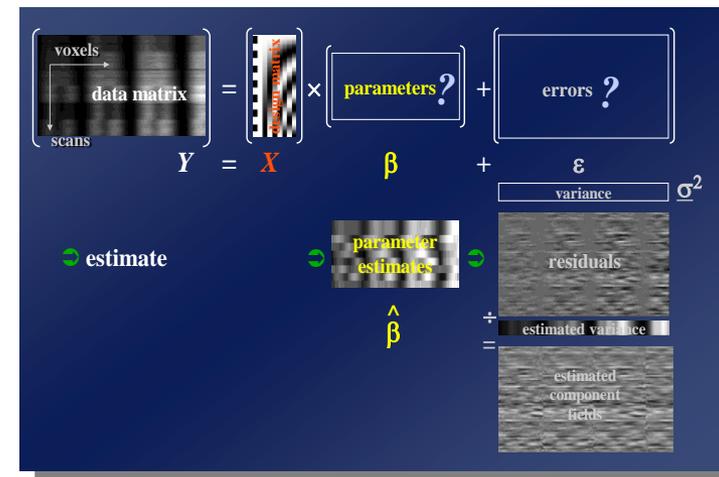

Eg: 10 voxels, 2.5 FWHM, 4 RESELS

The number of resels is similar, but not identical to the number independent observations.

Smoothness estimated from spatial derivatives of standardised residuals:

Yields an RPV image containing local roughness estimation.

Random Field intuition

Corrected p -value for statistic value t

$$\begin{aligned} p_c &= p(\max T > t) \\ &\approx E[\chi_t] \\ &\propto \lambda(\Omega) |\Lambda|^{1/2} t \exp(-t^2/2) \end{aligned}$$

- ❑ Statistic value t increases ?
 - p_c decreases (better signal)
- ❑ Search volume increases ($\lambda(\Omega) \uparrow$) ?
 - p_c increases (more severe correction)
- ❑ Smoothness increases ($|\Lambda|^{1/2} \downarrow$) ?
 - p_c decreases (less severe correction)

Random Field: Unified Theory

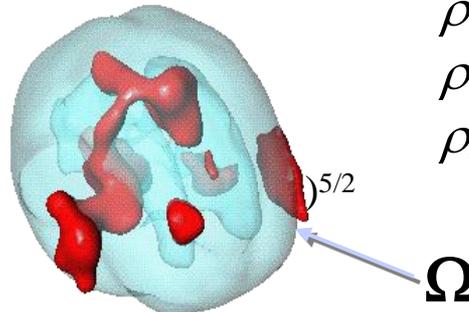

General form for expected Euler characteristic

- t , F & χ^2 fields
- restricted search regions
- D dimensions

$$E[\chi_u(\Omega)] = \sum_{d=0}^D R_d(\Omega) \rho_d(u)$$

$R_d(\Omega)$: d -dimensional Lipschitz-Killing curvatures of Ω (\approx *intrinsic volumes*):
 – *function of dimension, space Ω and smoothness:*

$R_0(\Omega) = \chi(\Omega)$ Euler characteristic of Ω
 $R_1(\Omega) =$ resel diameter
 $R_2(\Omega) =$ resel surface area
 $R_3(\Omega) =$ resel volume

$\rho_d(u)$: d -dimensional EC density of the field
 – *function of dimension and threshold, specific for RF type:*

E.g. Gaussian RF:

$$\rho_0(u) = 1 - \Phi(u)$$

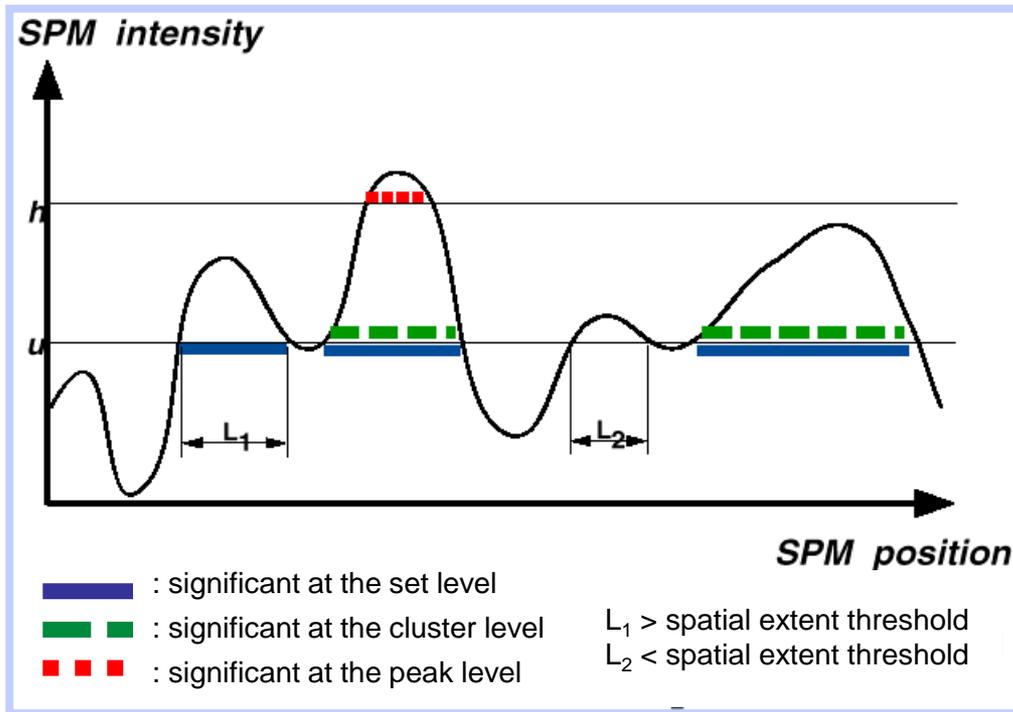

$$\rho_1(u) = (4 \ln 2)^{1/2} \exp(-u^2/2) / (2\pi)$$

$$\rho_2(u) = (4 \ln 2) u \exp(-u^2/2) / (2\pi)^{3/2}$$

$$\rho_3(u) = (4 \ln 2)^{3/2} (u^2 - 1) \exp(-u^2/2) / (2\pi)^2$$

$$\rho_4(u) = (4 \ln 2)^2 (u^3 - 3u) \exp(-u^2/2) /$$

Peak, cluster and set level inference

Sensitivity

Regional specificity

Peak level test:
height of local maxima

Cluster level test:
spatial extent above u

Set level test:
number of clusters above u

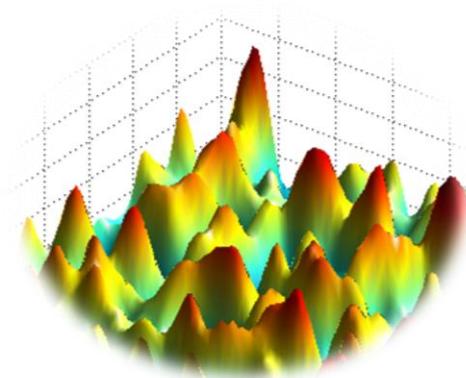

Random Field Theory

- ❑ The statistic image is assumed to be a good lattice representation of an underlying continuous stationary random field.

Typically, FWHM > 3 voxels

(combination of intrinsic and extrinsic smoothing)

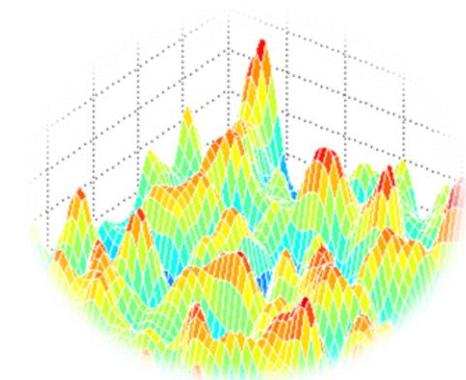

- ❑ RFT conservative for low degrees of freedom (always compare with Bonferroni correction).

Afford little power for group studies with small sample size.

- ❑ *A priori* hypothesis about where an activation should be, reduce search volume \Rightarrow Small Volume Correction:

- mask defined by (probabilistic) anatomical atlases
- mask defined by separate "functional localisers"
- mask defined by orthogonal contrasts
- (spherical) search volume around previously reported coordinates

Conclusion

- ❑ There is a ***multiple testing problem*** and *corrections* have to be applied on p -values (for the volume of interest only (see SVC)).
- ❑ Inference is made about ***topological features*** (peak height, spatial extent, number of clusters).
Use results from the ***Random Field Theory***.
- ❑ **Control of *FWER*** (probability of a false positive anywhere in the image): very specific, not so sensitive.
- ❑ **Control of *FDR*** (expected proportion of false positives amongst those features declared positive (the *discoveries*)): less specific, more sensitive.
